JAVASCRIPT FRAMEWORKS ARE NOT FOR EVERY SYSTEM

Suoranta.WebApp

Classic Technologies, Modern User Experience

Document Version 11/2026 By Lauri Suoranta

Background (1/2)

"Paradigmatic Evolution" in Web Development:

- 2000s: Fully server-side HTML generation (PHP).
- 2010s: Model-View-Controller (ASP.NET MVC).
- 2020s: Single Page App (SPA) frameworks (Angular, React, …).

None has really replaced its predecessor. Full paradigm "upgrade" of an existing application or service seems very rare.

- Does not apply to back-end support infrastructure like databases.

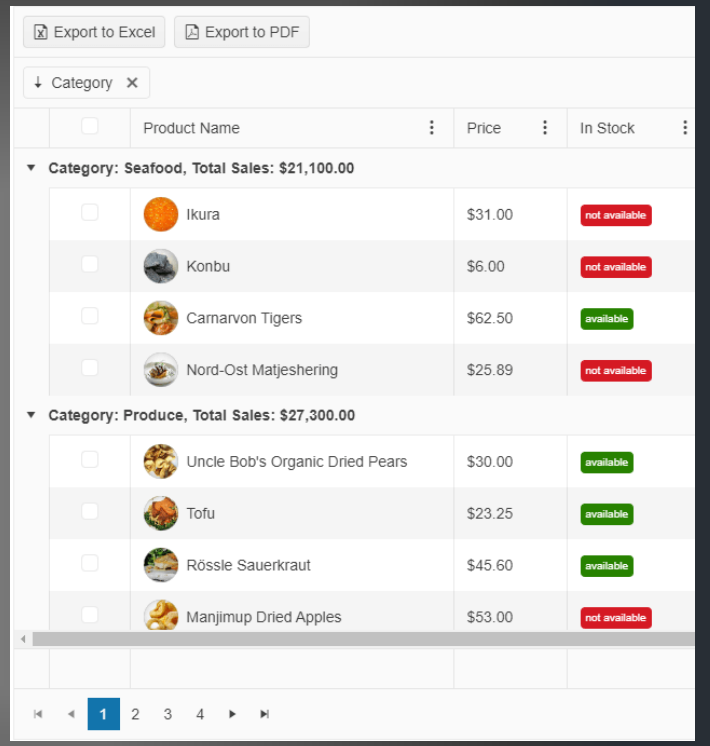

Running SPAs in traditional web browser makes little sense.

- Browser's buttons and other functionality make mess in SPAs.

Background (2/2)

Suoranta.WebApp began as an effort to alleviate shortcomings of Telerik UI for ASP.NET MVC[1] (Kendo UI) in controller (server) interactions.

- Issues mostly not related to pure Kendo UI, but very incomplete MVC integration in Telerik UI.
- Kendo UI and WebApp are no longer closely coupled, though WebApp and EnterpriseLib work well with Kendo Grid in data-centric apps with complex use cases, especially those involving data input.

Grid: a component of much larger Kendo library, but one of the most essential.

[1] Kendo UI is a well-established collection of JavaScript UI components developed by Telerik. Kendo UI components are independent of any particular web development framework. Telerik UI for ASP.NET MVC is supposed to ease the configuration of Kendo components on ASP.NET MVC.

OVERVIEW OF SUORANTA.WEBAPP

Widgets Framework[1]

Fluent Bootstrap & custom widget builders.

Strongly typed fluent builders for essential HTML. Integrate into CSHTML.

WebApp JavaScript Modules

HTML/JavaScript modern component development based on the latest W3C specifications.

WebApp.View (Razor)[1][2]

AjaxHelper(<T>)

+ JS support modules

HtmlHelper(<T>)

KendoHelper

TagHelper

UrlHelper

WebViewPage(<T>)

[1] See the API documentation for details: suoranta.github.io/ApiDocs/

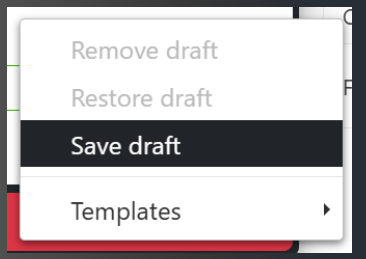

[2] Derive the original Razor classes where such exist, allowing backward compatibility.

WebApp & Razor

To make most out of WebApp, the default base class for Views should be switched from MVC's default to WebApp. This enables WebApp's Razor features without the need for individual `@inherits` statements.

WebApp's builders integrate into CSHTML with `using` statements[1]:

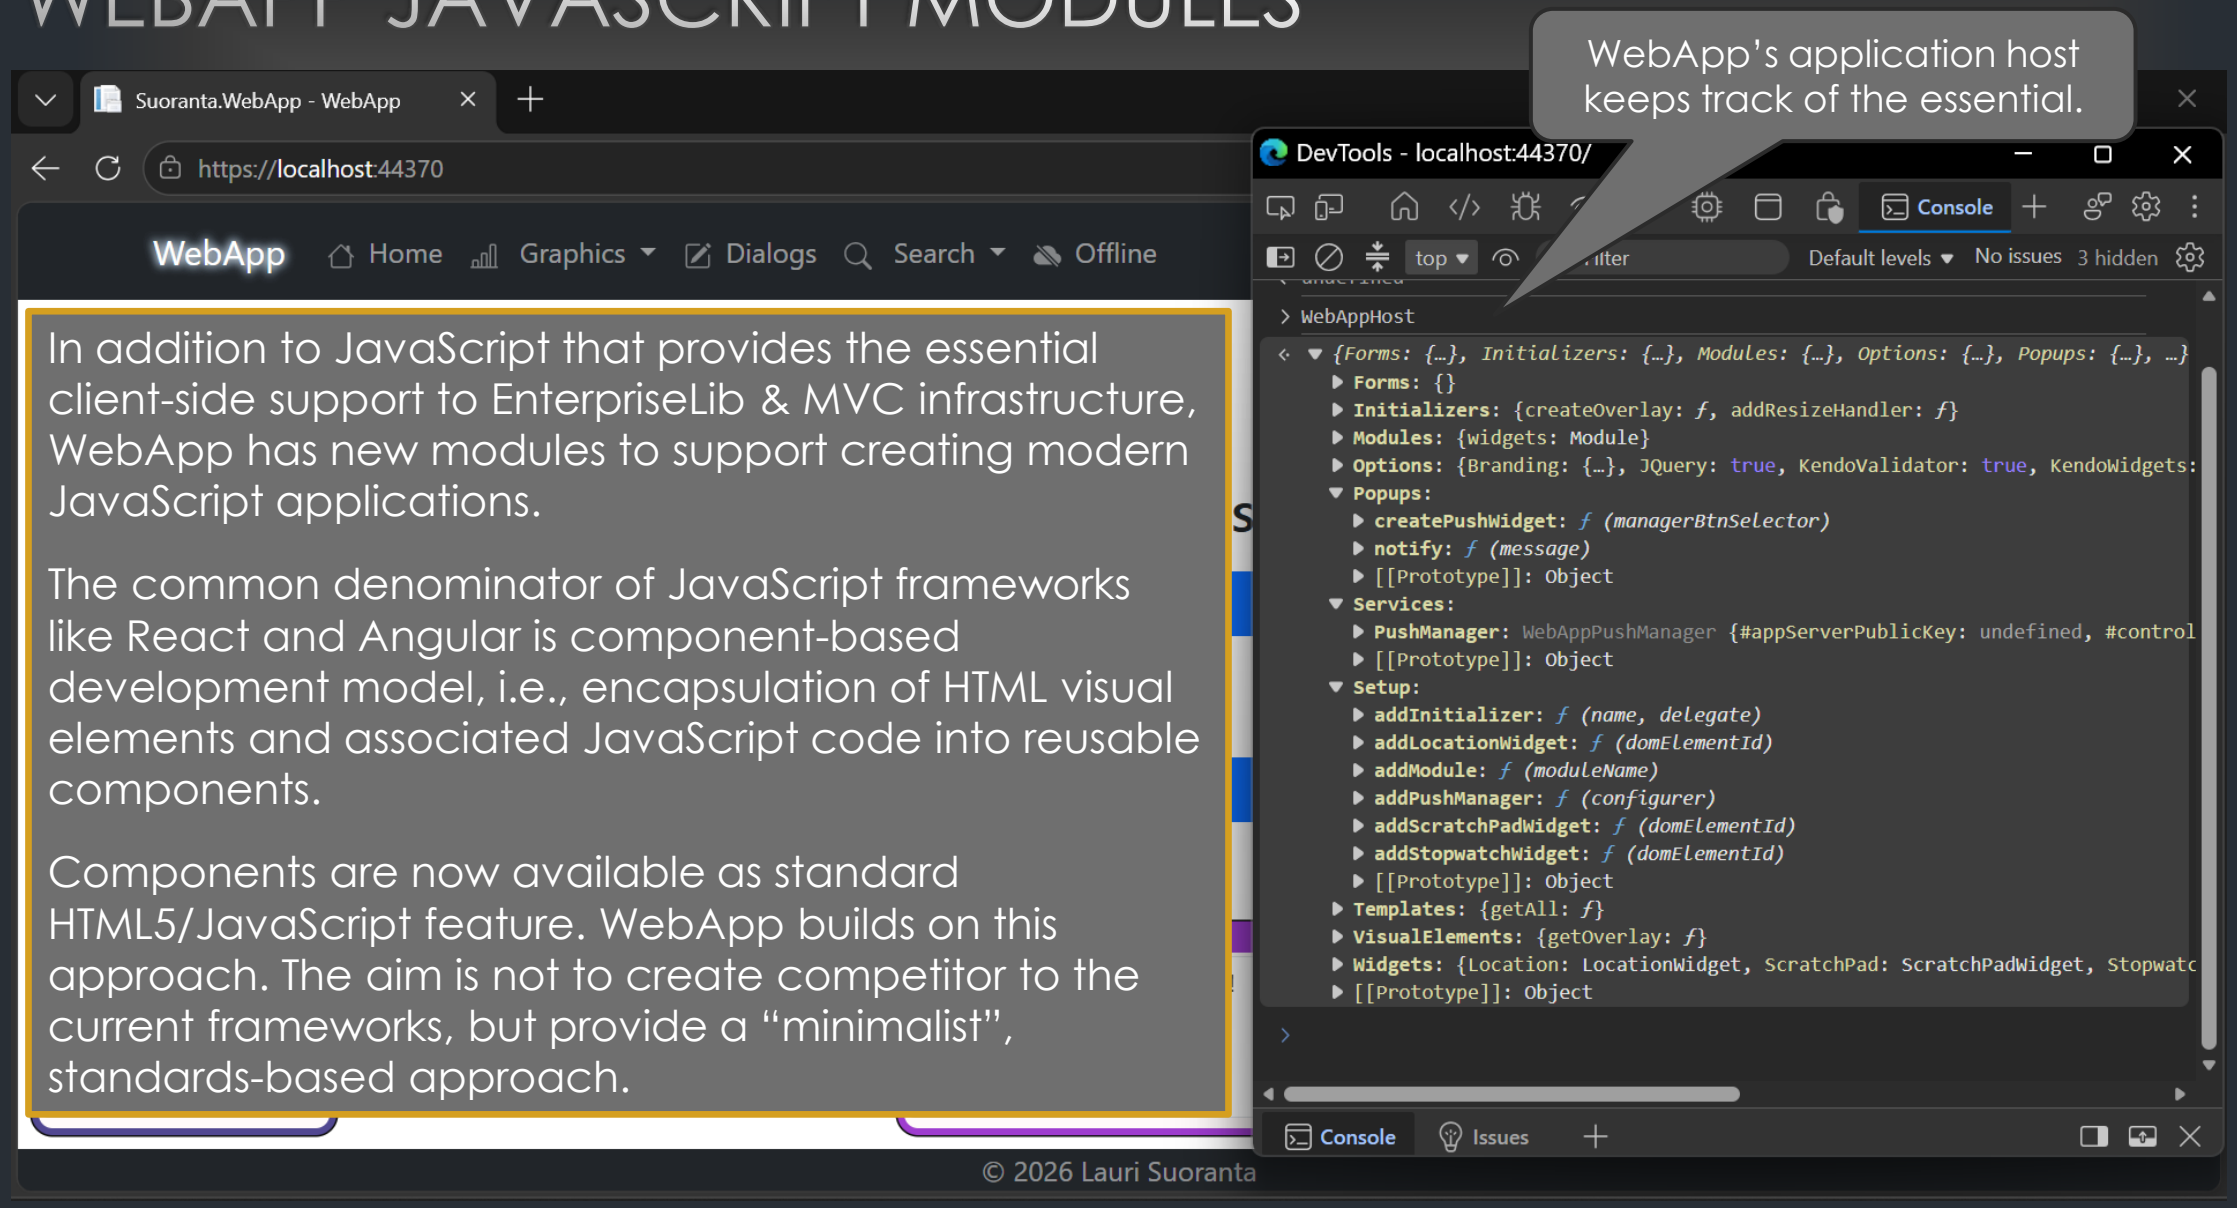

```
(var builder = BeginForm(…).AddContextMenu())
{
    <!-- Add custom content. The builder can also be invoked. -->
}
```

WebApp client-side can integrate partial views into main document's DOM very dynamically, including loading scripts within the partial.

[1] In the example, the form uses View's DTO type, but unlike in the original, this is not an imperative. A View Can have multiple async forms, each with its own type. The extensible context menu for forms has built-in feature for saving drafts and templates.

WEBAPP JAVASCRIPT MODULES

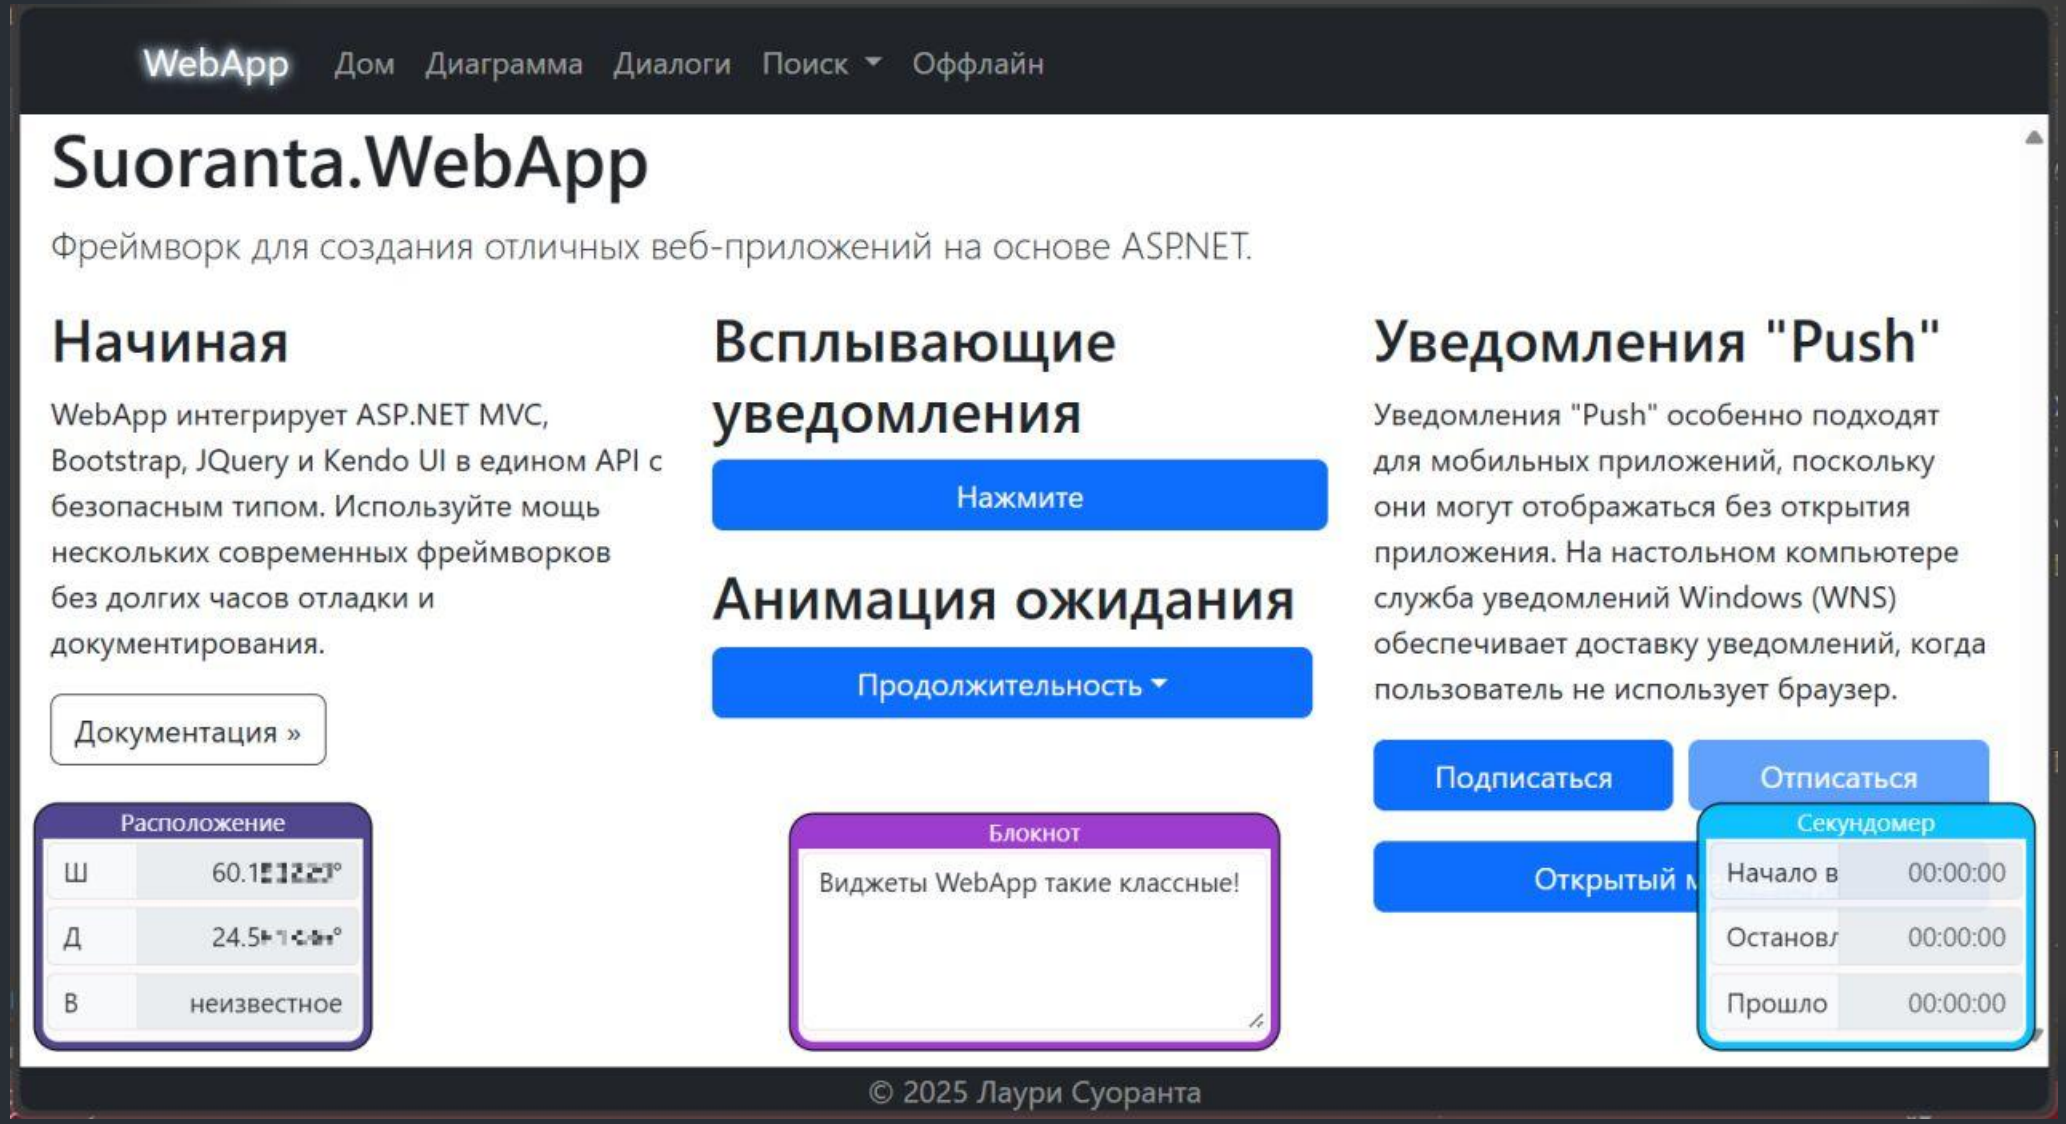

In addition to JavaScript that provides the essential client-side support to EnterpriseLib & MVC infrastructure, WebApp has new modules to support creating modern JavaScript applications.

The common denominator of JavaScript frameworks like React and Angular is component-based development model, i.e., encapsulation of HTML visual elements and associated JavaScript code into reusable components.

Components are now available as standard HTML5/JavaScript feature. WebApp builds on this approach. The aim is not to create competitor to the current frameworks, but provide a "minimalist", standards-based approach.

MULTILANGUAGE SUPPORT

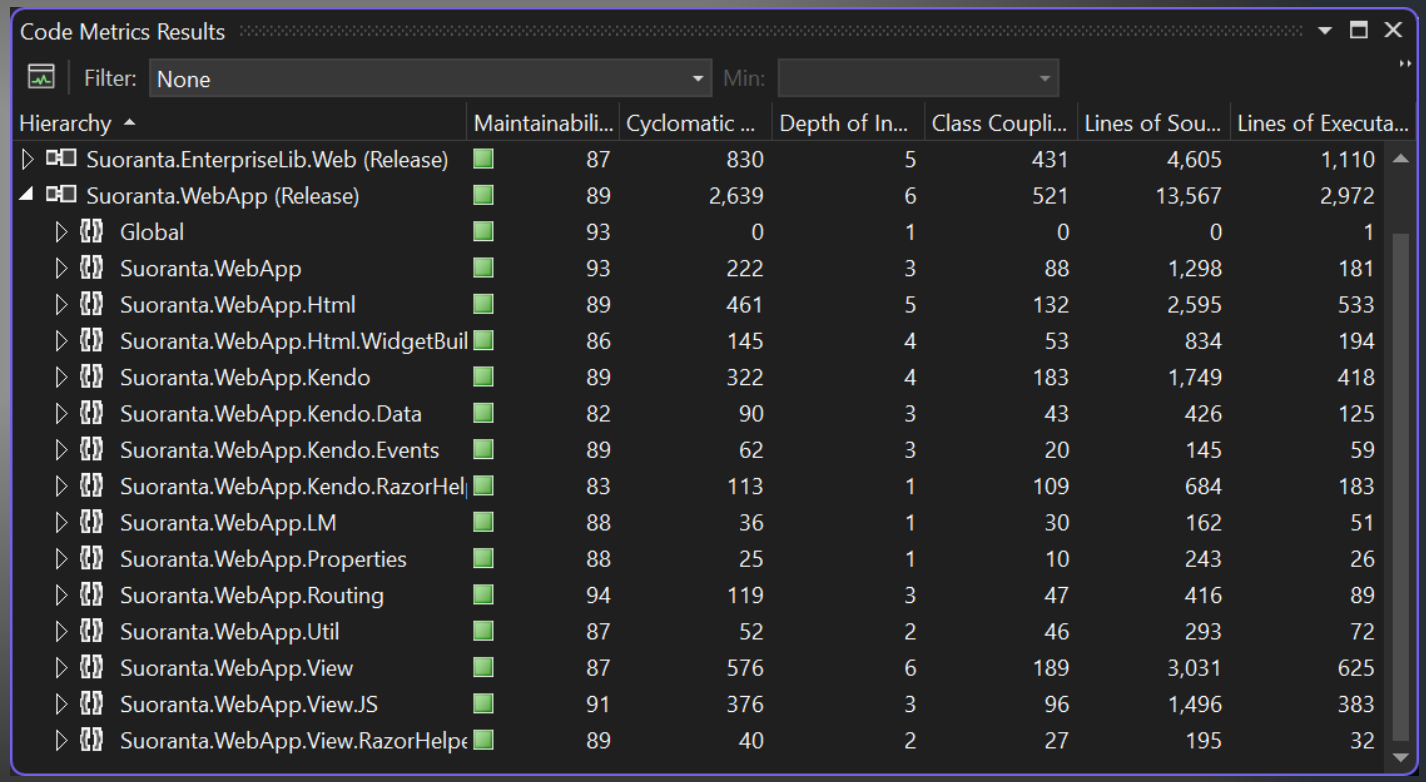

Conclusion

Any one paradigm is unlikely to be ideal for all kinds of online services and applications.

The originally chosen paradigm tends to stick in some form as full redevelopment is rare.

WebApp supports gradual evolution and evolves itself.
